

a processor electrically coupled to the crown by the shaft, and further electrically coupled to the enclosure; and  
a display carried by the enclosure and configured to display graphical objects, wherein the processor is configured to:  
determine, based on an electrical signal received from a body of the user by at least one of the enclosure or the crown, an electrocardiograph (ECG) of the user; and  
in response to determining the ECG of the user, cause a graphical object related to the ECG to be displayed on the display.

**41.** The electronic watch of claim **40**, wherein:  
the electronic watch further comprises a translation sensor configured to detect a translational input from the crown; and  
the processor is electrically coupled to the crown by the shaft and the translation sensor.

**42.** The electronic watch of claim **41**, wherein the electronic watch further comprises a rotation sensor configured to detect a rotational input from the crown.

**43.** The electronic watch of claim **42**, wherein the processor is further configured to modify the graphical object in response to each of the rotational input and the translational input.

**44.** The electronic watch of claim **40**, wherein:  
the display is a touch-sensitive display configured to receive a touch input; and  
the processor is further configured to modify the graphical object in response to the touch input.

**45.** The electronic watch of claim **40**, wherein:  
the processor is further configured to:  
cause one of the enclosure or the crown to apply a voltage at the wrist or the finger; and  
cause the other of the enclosure or the crown to receive the electrical signal from the body of the user; and  
the processor determines the ECG of the user by comparing one or more characteristics of the electrical signal with one or more characteristics of the applied voltage.
